ORBIT DETERMINATION AND ANALYSIS FOR AUREOLE 2 ROCKET
AT 27:2 RESONANCE

bу

A. N. Winterbottom

160

#### SUMMARY

Aureole 2 rocket (1973-107B) was launched on 26 December 1973 into an orbit of inclination 74% and eccentricity 0.1 and has an estimated lifetime of 30 years. The orbit has been determined from observations for 90 epochs between September 1983 and December 1984, during which time the orbit was expected to be influenced significantly by the effects of 27:2 resonance with the Earth's gravitational field; exact resonance occurred on 28 April 1984. The observations numbered nearly 7400, of which 344 were from the Hewitt cameras of the University of Aston which are sited at Herstmonceux in England, and Siding Spring in Australia. The orbital inclination and eccentricity of the orbits derived had standard deviations corresponding on average to positional accuracies of 130 m cross-track and 80 m in perigee distance.

The variations in inclination and eccentricity have been analysed individually to determine values of two pairs of lumped harmonics of order 27 from each parameter; when these parameters were fitted simultaneously they gave three pairs of harmonics with standard deviations corresponding to accuracies of approximately 2.5 cm in good height.

### 1 INTRODUCTION

When the satellite Aureole 2 was launched on 26 December 1973, its rocket, designated 1973-107B, entered an orbit with an estimated lifetime of 30 years. The rocket is cylindrical in shape, 7.4 m long with a diameter of 2.4 m, and has a mass of about 2200 kg. Its initial orbital parameters were: inclination 74.01°, perigee and apogee heights 396 and 1965 km respectively, and nodal period 109.02 min.

In April 1984, Aureole 2 rocket passed through the condition of 27.2 resonance, ie the track over the Earth repeated every 2 days after 27 revolutions. If the passage through resonance of an orbiting body is slow enough, the effects of 27th-order harmonics in the geopotential can build up and result in an appreciable perturbation to some of the orbital elements. Thus measurement of these resultant perturbations provides a good method for accurately determining the appropriate lumped geopotential harmonics. The aim of this Report is to compute accurate orbits from observations made during the time when the 27:2 resonance with the geopotential was affecting the orbit and to evaluate lumped geopotential harmonics of order 27 from the changes they produced in the orbital inclination and eccentricity; this is the first occasion on which 27th-order harmonics have been obtained from resonant satellite orbit analysis. The orbit was determined between September 1983 and December 1984 from radar and optical observations using the RAE orbit refinement program PROP, in the PROP6 version<sup>2</sup>.

### 2 OBSERVATIONS AND ORBITS

### 2.1 Data sources

The orbit of 1973-107B has been determined at 90 epochs between 18 September 1983 and 22 December 1984 from 7383 observations, not including those rejected in the orbit determinations.

These observations came from four different sources, the most accurate being those from the University of Aston's Hewitt cameras at the Royal Greenwich Observatory, Herstmonceux, and at Siding Spring in Australia; 344 of these observations were used in 27 of the 90 orbits. The second group consisted of 496 visual observations made by volunteer observers reporting to the Earth Satellite Research Unit at the University of Aston. The third and largest group, of 4200 radar observations, were made by the US Navy Navspasur system, kindly supplied by the US Naval Research Laboratory and the fourth group consisted of 2343 radar observations from the tracking station at RAF Fylinguales.

### 2.2 Observational accuracy

The rms residuals of the observations have been calculated using the RAE computer program ORES<sup>3</sup>, and have been distributed to the observers. Table I gives the residuals for selected observing stations with at least five observations accepted in the final orbit determinations. The US Navy observations from station 29 are geocentric, and if they were given in the same form as the topocentric observations, their angular rms residuals would increase by a factor of

<sup>\*</sup> Geocentric

<sup>†</sup> Hewitt cameras

NB Figures in brackets indicate the number of observations used to calculate the rms residuals; *ie* those observations with residuals less than twice the rms value.

between 5 and 10. In calculating the rms residuals for the visual observers, observations with residuals greater than twice the rms have been omitted, the numbers used being shown in brackets. This gives a truer impression of the normal accuracy of the observer, as it eliminates observations marred by poor visibility and possible deficiencies in orbital fitting.

The rms residuals of the Hewitt cameras are 5 seconds of arc from 203 observations by the Herstmonceux camera and 6 seconds of arc from 117 observations by the Siding Spring camera. Since the residuals combine the orbital and observational errors, and the orbital model is less accurate than the observations, the observational errors of the Hewitt cameras are likely to be less that their rms residuals, and 2 seconds of arc would be an accuracy consistent with the results.

### 2.3 Orbits and orbital accuracy

Orbits were determined using RAE's orbit refinement program PROP, in the PROP6 version, and orbital elements at the 90 epochs together with their standard deviations are listed in Table 2 on page 16. The epoch for each orbit is at 00 hours on the day indicated, and the PROP program fits the mean anomaly M by a polynomial of the form

$$M = M_0 + M_1 t + M_2 t^2 + M_3 t^3 + M_4 t^4 + M_5 t^5 , \qquad (1)$$

where t is the time measured from epoch and the number of M-coefficients used depends on the drag. For 1973 107B, with orbital eccentricity approximately 0.1, and perigee and apogee heights of about 400 and 1700 km respectively,  $M_0-M_2$  were sufficient for 87 of the 90 orbits. The other three orbits required the use of coefficients  $M_0-M_3$ .

The value of  $\epsilon$ , the parameter which indicates the measure of fit of the observations to the orbit, varied between 0.33 and 0.83 with an average value of 0.56, showing that all of the orbits were fitted satisfactorily. The average number of observations in an orbit determination was 82, spread over a time interval averaging 4.9 days.

The average standard deviation in eccentricity e for the 90 orbits is 0.000011, equivalent to an error in perigee distance of 80 m; the average for the 27 orbits containing Hewitt camera observations was 0.000008. The perigee distances Q = a(1 - e) from Table 2 are plotted in Fig 1, and exhibit the usual sinusoidal oscillations dependent on the argument of perigee,  $\omega$ ; also plotted

in Fig 1, but on a larger scale, are the values of Q', the perigee distance after removal of lunisolar and zonal harmonic perturbations.

The mean standard deviation in inclination for the 90 orbits is  $0.0010^{\circ}$ , corresponding to an error of 130 m in cross-track distance; for the 27 orbits containing Hewitt camera observations the accuracy is again better, the average standard deviation being  $0.0008^{\circ}$ .

### 3 THEORY FOR THE RESONANCE EFFECTS

The theory has been given in detail in Ref 4 and will only be summarized here. The longitude-dependent part of the geopotential at an exterior point  $(r, \theta, \lambda)$  is written as

$$\frac{\mu}{r} \sum_{\ell=2}^{\infty} \sum_{m=1}^{\ell} \left(\frac{R}{r}\right)^{\ell} P_{\ell}^{m} \left(\cos \theta\right) \left\{ \overline{C}_{\ell m} \cos m\lambda + \overline{S}_{\ell m} \sin m\lambda \right\} N_{\ell m} , \qquad (2)$$

where r is the distance from the Earth's centre,  $\theta$  is co-latitude,  $\lambda$  is longitude (positive to the east),  $\mu$  is the gravitational constant for the Earth (398600 km<sup>3</sup>/s<sup>2</sup>), R is the Earth's equatorial radius (6378.1 km),  $P_{\ell}^{m}$  (cos  $\theta$ ) is the associated Legendre function of order m and degree  $\ell$ , and  $\overline{C}_{\ell m}$  and  $\overline{S}_{\ell m}$  are the normalized tesseral harmonic coefficients, of which only those of order m = 27 are relevant here. The normalizing factor  $N_{\ell m}$  is given by

$$N_{\ell m}^{2} = \frac{2(2\ell + 1)(\ell - m)!}{(\ell + m)!}.$$
 (3)

The rate of change of inclination i caused by a relevant pair of coefficients,  $\bar{c}_{lm}$  and  $\bar{s}_{lm}$ , near  $\beta:\alpha$  resonance may be written (ignoring terms of order  $e^2$ ) as

$$\frac{di}{dt} = \frac{n}{\sin i} \left( \frac{R}{a} \right)^{k} \tilde{F}_{kmp} G_{kpq} (k \cos i - m) \Re \left[ j^{k-m+1} (\tilde{C}_{km} - j\tilde{S}_{km}) \exp \left\{ j (\gamma \Phi - q \omega) \right\} \right] , \qquad ....(4)$$

where  $\overline{F}_{\ell mp}$  is Allan's normalized inclination function  $^6$ ,  $^6$   $^6$  is a function of eccentricity for which explicit forms and a computer program are given in Ref 4,  $^6$  denotes 'real part of' and  $j=\sqrt{-1}$ . The resonance angle  $^6$  is defined by the equation

$$\Phi = \alpha(\omega + M) + \beta(\Omega - \nu) , \qquad (5)$$

where  $\omega$  is the argument of perigee, M the mean anomaly,  $\Omega$  the right ascension of the node and  $\nu$  the sidereal angle. The indices  $\gamma$ , q, k and p in equation (4) are integers, with  $\gamma$  taking the values 1, 2, 3 ... and q the values 0,  $\pm 1$ ,  $\pm 2$ , ...; the equations linking  $\ell$ , m, k and p are:  $m \approx \gamma \beta$ ;  $k = \gamma \alpha - q$ ;  $2p = \ell - k$ .

Here  $\beta$  = 27 and  $\alpha$  = 2, and as we shall only consider the  $\gamma$  = 1 terms, which are usually dominant, we have m = 27 and k = 2 - q. The values of  $\ell$  to be taken must be such that  $\ell \ge m$  and  $(\ell - k)$  is even. The successive coefficients which arise (for given  $\gamma$  and q) may be grouped into a lumped harmonic, written as

$$\tilde{c}_{m}^{q,k} = \sum_{\ell} Q_{\ell}^{q,k} \tilde{c}_{\ell m}^{q,k}, \qquad \tilde{s}_{m}^{q,k} = \sum_{\ell} Q_{\ell}^{q,k} \tilde{s}_{\ell m}^{q,k}, \qquad (6)$$

where  $\ell$  increases in steps of 2 from its minimum permissible value  $\ell_0$ , and the  $Q_{\ell}$  are constant coefficients, with  $Q_{\ell 0} = 1$ . The values of the  $Q_{\ell}$  can be obtained from equation (4), and R.H. Gooding has written a computer program PROF for their evaluation.

The rate of change of eccentricity produced by a relevant pair of coefficients  $\overline{C}_{lm}$  and  $\overline{S}_{lm}$  near  $\beta:\alpha$  resonance may be written

$$\frac{\mathrm{d}e}{\mathrm{d}t} = n \left(\frac{R}{a}\right)^{\ell} \bar{F}_{\ell mp} G_{\ell pq} \left\{\frac{q - \frac{1}{2}(k + 3q)e^{2}}{e}\right\} \Re \left[j^{\ell - m + 1}(\bar{C}_{\ell m} - jS_{\ell m}) \exp j(\gamma \Phi - q\omega)\right],$$

$$\dots (7)$$

where terms of order e have again been ignored.

As the  $G_{\ell pq}$  are of order  $e^{|q|}$ , it turns out that, for orbits of eccentricity less than 0.1, the leading terms in equation (4) are those with  $q\approx 0$  and  $q=\pm 1$ , while the main terms in (7) are those with  $q=\pm 1$ . These are the only terms that will be evaluated in the analysis of 1973-107B.

The explicit forms of equations (4) and (7) are given in Ref 4 for the 31:2 and 29:2 resonances, but not for the 27:2 resonance. The equation for di/dt at 27:2 resonance, with q = 0 and  $q = \pm 1$ , is

$$\frac{di}{dt} = n \left(\frac{R}{a}\right)^{27} \left[ \left(\frac{R}{a}\right)^{\frac{1}{7}} \tilde{F}_{28,27,13}^{G_{28,13,0}} (27 \text{ cosec } i-2 \text{ cot } i) \left\{ \tilde{S}_{27}^{0,2} \sin \phi + \tilde{C}_{27}^{0,2} \cos \phi \right\} \right] + \tilde{F}_{27,27,13}^{G_{27,13,1}} (27 \text{ cosec } i-\cot i) \left\{ \tilde{C}_{27}^{1,1} \sin(\phi - \omega) - \tilde{S}_{27}^{1,1} \cos(\phi - \omega) \right\} + \tilde{F}_{27,27,12}^{G_{27,12,-1}} (27 \text{ cosec } i-3 \cot i) \left\{ \tilde{C}_{27}^{-1,3} \sin(\phi + \omega) - \tilde{S}_{27}^{-1,3} \cos(\phi + \omega) \right\} \right].$$

A factor  $(1 - e^2)^{-\frac{1}{2}}$  should be introduced on the right-hand side if terms of order  $e^2$  are required. The equation for de/dt, with  $q = \pm 1$  terms only, is

$$\frac{de}{dt} = \frac{n}{e} \left( \frac{R}{a} \right)^{27} \left[ -\bar{F}_{27,27,13}^{G} G_{27,13,1} \left\{ \bar{C}_{27}^{1,1} \sin(\phi - \omega) - \bar{S}_{27}^{1,1} \cos(\phi - \omega) \right\} + \bar{F}_{27,27,12}^{G} G_{27,12,-1} \left\{ \bar{C}_{27}^{-1,3} \sin(\phi + \omega) - \bar{S}_{27}^{-1,3} \cos(\phi + \omega) \right\} \right] . \quad (9)$$

Here, with  $\gamma\alpha$  = 2 and q  $\neq$  0, the factors that need to be introduced on the right-hand side of (9) to take account of terms of order  $e^2$  are given by  $\{1-e^2(1+1/q)+0(e^4)\}$ , from Ref 4. Thus for the first term in curly brackets in (9) (q = 1), the factor is  $\{1-2e^2+0(e^4)\}$ , and for the second term (q = -1), the factor is  $\{1+0(e^4)\}$ .

# 4 ANALYSIS OF THE VARIATIONS IN INCLINATION AND ECCENTRICITY

### 4.1 Progress through resonance

Variations in  $\dot{\Phi}$  during the period covered by this study are shown in Fig 2. The increase in  $\dot{\Phi}$ , from about -10 deg/day through to +7 deg/day, proceeds quite steadily, but is rather slower after the exact resonance, which occurs on 28 April 1984. Progress through resonance is not as slow as would ideally be hoped for: it is 8 times faster than for the recent analysis of 1968-40B at 29:2 resonance, so the resulting perturbations and derived coefficients cannot be expected to be so accurate as those obtained from 1968-40B.

# 4.2 Analysis of inclination

The raw values of inclination given in Table 2 need to be cleared of perturbations due to zonal harmonics and lunisolar effects: this has been done by use of the PROD computer program with integration at 1-day intervals.

Perturbations due to the  $J_{2,2}$  harmonic are recorded within each PROP run and have also been removed. Fig 3 shows the resulting values of i, with sd.

These values of inclination were then fitted with the computer program THROE  $^9$ , within which the effects of atmospheric rotation are also removed (the value used for the atmospheric rotation rate  $\Lambda$  was 1.00, in conformity with Ref 10). At first the fittings were made with all three pairs of values of  $(\gamma,q)$  in equation (4), that is,  $(\gamma,q)=(1,0)$ , (1,1) and (1,-1), as in equation (8). However, it was found that the values for  $(\gamma,q)=(1,-1)$  were small and indeterminate, so these terms were dropped. It also became apparent from the THROE runs that a number of the orbits fitted badly, as indeed is obvious from Fig 3. Values of inclination which had residuals greater than  $2\varepsilon$ , where  $\varepsilon$  is the overall measure of fit, were relaxed by doubling the standard deviation and, if necessary, quadrupling it. Also the first four orbits were omitted. As a result of these procedures 12 values had their standard deviations doubled and two values had quadrupled standard deviations. The fitting began at MJD 45628, covered 85 orbits and ended at MJD 46051, the last orbit also being omitted, as it was ill-fitting. The overall measure of fit,  $\varepsilon$ , was 1.17, which is quite satisfactory.

Although the simultaneous fitting of i and e will be preferred (see section 4.4), the values of the  $(\gamma,q) = (1,0)$  terms from the fitting of i alone should be fairly satisfactory. They are:

$$10^{9\hat{c}_{27}^{0,2}} = 22.4 \pm 12.4$$
,  $10^{9\hat{c}_{27}^{0,2}} = 30.8 \pm 10.2$ . (10)

The 'hats' over the lumped harmonics indicate that these are the values emerging from THROE, within which  $G_{\ell pq}$  is replaced by an approximation  $\hat{G}_{\ell pq}$ . See Ref 4 and section 4.4. (The values of  $(\bar{C},\bar{S})_{27}^{1,1}$  are not given as they are subsidiary terms and are normally better determined from e.)

### 4.3 Analysis of eccentricity

As the eccentricity of 1973-107B is quite large, and decreases appreciably due to drag during the resonance, it is better to work with the perigee distance, which is much less affected by drag. The lower graph in Fig 1 gives the raw values of a(1 - e), showing the characteristic oscillation due to odd zonal harmonics, which has an amplitude near 7 km. The upper graph in Fig 1 shows the values after removal of zonal harmonic and lunisolar perturbations. These values, denoted by Q', should show the effects of air drag and of resonance only. For the fitting by THROE, it is convenient to define a revised value of e, erev say, based on Q'. Thus

$$e_{rev} = 1 - Q'/\bar{a}$$
 , (11)

where  $\bar{a}$  is the mean value of a during the orbit determinations. To a first approximation the decrease in Q' due to drag at any stage in the orbit determinations is given by  $\frac{1}{2}H\ln(e_0/e)$ , where H is the density scale height,  $e_0$  the initial eccentricity and e its current value (corrected to  $\omega = \omega_0$ ). On comparing values of e at similar values of  $\omega$  in Table 1, the decrease in e between MJD 45595 and 45983 is found to be by a factor 1.0112, and, on taking H = 50 km, this gives a decrease of 0.28 km in Q', which translates into an average increase of almost exactly  $10^{-7}$  per day in e. Thus a new value of e,  $e^*$  say, cleared of air drag, may be defined as

$$e^* = e_{rev} - 10^{-7} (t - t_0)$$
 (12)

(In practice the correction was taken as  $-\frac{1}{2}N \times 10^{-6}$ , where N is the orbit number.)

The resulting values of e\* were fitted by THROE with  $(\gamma,q)=(1,1)$  and (1,-1). As with i, the first four values were omitted, and a number of the standard deviations were relaxed. The two anomalous values at MJD 46033 and 46037 (see Fig 1) were allocated standard deviations of 0.0001, and eight other standard deviations which exceeded  $2\varepsilon$  were relaxed by a factor of 2. The overall measure of fit,  $\varepsilon$ , then had the value 2.66: this is rather high, but not unusually so, because values of  $\varepsilon$  near 2 often arise when fitting eccentricity<sup>7</sup>.

# 4.4 Fitting of i and e simultaneously

As both inclination and eccentricity required the  $(\gamma,q)=(1,1)$  term, it seemed best to fit them simultaneously with R.H. Gooding's SIMRES program. The SIMRES fitting was made with  $(\gamma,q)=(1,0),(1,1)$  and (1,-1) and the eccentricity fitting was given a lower weighting, in accordance with the ratio of the values of  $\varepsilon$  in the THROE fittings for i and e: the weighting factor was 1.848. The overall measure of fit for the SIMRES fitting was 1.362, and the individual values of  $\varepsilon$  for i and e were 1.32 and 2.96, as compared with 1.17 and 2.66 for the individual fittings. Thus the fittings are not much worse, and the combined fitting is to be recommended because the  $(\gamma,q)=(1,1)$  term is significant for both i and e, and SIMRES provides an 'average'. The values of the harmonics that emerge are:

$$10^{9} \hat{c}_{27}^{0,2} = 18.4 \pm 15.8 , \qquad 10^{9} \hat{s}_{27}^{0,2} = 26.3 \pm 12.3$$

$$10^{9} \hat{c}_{27}^{1,1} = 14.4 \pm 15.1 , \qquad 10^{9} \hat{s}_{27}^{1,1} = -9.1 \pm 13.3 . \qquad (13)$$

$$10^{9} \hat{c}_{27}^{-1,3} = 14.5 \pm 8.7 , \qquad 10^{9} \hat{s}_{27}^{-1,3} = 2.4 \pm 11.2$$

It may be noted that the values of  $(\hat{C}, \hat{S})_{27}^{0,2}$  in equations (10) are consistent with those in (13).

The fittings of inclination and eccentricity are shown in Figs 4 and 5, where the standard deviations indicated are those after relaxation. It will be seen that in the combined fitting some of the residuals exceed  $2\epsilon$ : for example the residual for i at MJD 45734 is  $3.1(=2.3\epsilon)$ . Further readjustment of the relaxations was not attempted.

The values of C and S above have been given 'hats' (^) to indicate that they are the values emerging from SIMRES, in which the values of the G functions in equations (8) and (9) are replaced by an approximation  $\hat{G}$ . Thus if  $\tilde{C}_m^{q,k}$  is the correct value we have

$$\hat{G}_{l_0 p_0 q} \hat{\overline{C}}_m^{q,k} = C_{l_0 p_0 q} \overline{C}_m^{q,k} . \tag{14}$$

Thus the values of  $\hat{C}$  and  $\hat{S}$  in equations (13) have to be divided by  $C_{\ell_0 p_0 q}/\hat{C}_{\ell_0 p_0 q}$ , values of which (always >1) have been obtained from the computer program GQUAD<sup>4</sup>. For an orbit of such high eccentricity as 1973-107B and such high degree, the corrections are large: the three coefficients arising need to be divided by 3.323, 2.014 and 2.009 respectively.

Thus the values given in equations (13) may be rewritten as

$$10^{9}\overline{c}_{27}^{0,2} = 5.5 \pm 4.8 , \qquad 10^{9}\overline{s}_{27}^{0,2} = 7.9 \pm 3.7$$

$$10^{9}\overline{c}_{27}^{1,1} = 7.1 \pm 7.5 , \qquad 10^{9}\overline{s}_{27}^{1,1} = -4.5 \pm 6.6 \qquad . (15)$$

$$10^{9}\overline{c}_{27}^{-1,3} = 7.2 \pm 4.3 , \qquad 10^{9}\overline{s}_{27}^{-1,3} = 1.2 \pm 5.6$$

These are the final values of the lumped harmonics derived from analysis of 1973-107B.

For eccentricity, further THROE runs were made in which the value of the third zonal harmonic  $J_3$  was adjusted to minimize the value of  $\epsilon$ , and  $\epsilon$  was substantially reduced, from 2.66 to 1.85. However, this 'optimum- $J_3$ ' run for  $\epsilon$  and the THROE run for i, when combined in SIMRES, gave larger standard deviations for the lumped harmonics than those in (15): so the values (15) are preferred.

# 5 LUMPED HARMONICS IN TERMS OF INDIVIDUAL COEFFICIENTS $\bar{c}_{\ell m}, \bar{s}_{\ell m}$

The lumped harmonics  $(\overline{C},\overline{S})_{27}^{q,k}$  are expressible in terms of the individual coefficients  $(\overline{C},\overline{S})_{\ell m}$  by equations (6), and the computer program PROF evaluates the Q functions with adequate accuracy if e is very small. For 1973-107B, however, e  $\stackrel{\triangle}{=}$  0.087 and it is necessary to multiply each  $Q_{\ell}^{q,k}$  by a correction factor  $\xi$ , say, where  $\frac{1}{\ell}$ 

 $\xi = \frac{G_{lpq}}{\hat{G}_{lpq}} \cdot \frac{G_{l0}^{p_0q}}{G_{l0}^{p_0q}} = f \frac{G_{lpq}}{\hat{G}_{lpq}}, \qquad (16)$ 

and f is the factor by which the lumped harmonics had to be *multiplied*, namely 0.3009, 0.4965 and 0.4978 respectively, for the three pairs of harmonics in equations (15). Values of  $G_{\ell pq}/\hat{G}_{\ell pq}$  have been obtained from the computer program GQUAD for values of  $\ell$  up to 48 with  $\ell$  = 0.087 and the resulting values of  $\ell$  are given in Table 3. It is apparent that  $\ell$  departs greatly from 1 for

Table 3

Values of  $\xi$  for 1973-107B with e = 0.087

48	4.560	47	2.986

high values of  $\ell$ . The resulting expressions for the lumped harmonics in terms of the individual coefficients, after the values of Q from PROF have been multiplied by  $\xi$ , are as follows:

$$\bar{c}_{27}^{0,2} = \bar{c}_{28,27}^{0,139\bar{c}_{30,27}^{0,27}} - 0.319\bar{c}_{32,27}^{0,27} - 0.395\bar{c}_{34,27}^{0,27} - 0.256\bar{c}_{36,37}^{0,27} - 0.061\bar{c}_{38,27}^{0,27} + 0.089\bar{c}_{40,27}^{0,27} + 0.156\bar{c}_{42,27}^{0,27} + 0.144\bar{c}_{44,27}^{0,27},$$

$$(17)$$

$$\bar{c}_{27}^{1,1} = \bar{c}_{27,27} - 1.411\bar{c}_{29,27} - 0.785\bar{c}_{31,27} + 0.094\bar{c}_{33,27} + 0.541\bar{c}_{35,27} + 0.535\bar{c}_{37,27} + 0.278\bar{c}_{39,27} + 0.013\bar{c}_{41,27} - 0.204\bar{c}_{43,27} - 0.255\bar{c}_{45,27},$$
(18)

$$\bar{c}_{27}^{-1,3} = \bar{c}_{27,27} - 0.442\bar{c}_{29,27} - 0.695\bar{c}_{31,27} - 0.508\bar{c}_{33,27} - 0.188\bar{c}_{35,27} + 0.090\bar{c}_{37,27} + 0.244\bar{c}_{39,27} + 0.268\bar{c}_{41,27} + 0.196\bar{c}_{43,27} + 0.083\bar{c}_{45,27}$$
(19)

Similar equations apply for the S coefficients. Equation (17) has been terminated after 9 terms at  $\ell = 44$ , after which no numerical coefficient exceeds 0.1. Ten terms have been included for equations (18) and (19): in the neglected terms ( $\ell > 45$ ), no numerical coefficient exceeds 0.2.

#### 6 DISCUSSION

# 6.1 Comparison with comprehensive gravity-field models

A number of recent comprehensive models of the gravity field give values of  $\tilde{c}_{28,27}$ ,  $\tilde{c}_{30,27}$ , ...  $\tilde{c}_{36,27}$  which can be substituted into equation (17) to evaluate the lumped harmonic  $\tilde{c}_{27}^{0.2}$ , and similarly for S. The models chosen for comparison are, as in previous such comparisons  $^{7,11}$ , the Goddard Earth Model 10B (GEM 10B, Ref 12), the 1981 model of Rapp  $^{13}$ , and the European GRIM3-L1 (Ref 14). The newer models GEM T1 and GEM T2 are not included, because the values for

 $\ell$  = 28 to 36 are believed to be less reliable than for the other three models, being based on satellite data only. The values of the lumped harmonics obtained are given in Table 4.

Table 4

Values of lumped harmonics from 1973-107B and comprehensive models

	10 <sup>9</sup> c <sub>27</sub>	10 <sup>9</sup> 5 <sub>27</sub>	10 <sup>9</sup> c <sub>27</sub>	10 <sup>9</sup> 5 27	10 <sup>9</sup> c <sub>27</sub>	10 <sup>9</sup> s <sub>27</sub>
1973-107B	5.5 ± 4.8	7.9 ± 3.7	7.1 ± 7.5	-4.5 ± 6.6	7.2 ± 4.3	1.2 ± 5.6
GEM 10B	-13.4	3.1	9.3	-1.0	6.5	0.6
Rapp 1981	-5.6	6.2	17.6	-19.5	10.4	-8.7
GRIM 3-L1	-8.6	4.4	28.7	-16.8	15.6	-3.6

The estimated standard deviations of the values from the models in Table 4 are mostly near  $\pm 4$ , slightly lower than those from the resonance. The values in Table 4 vary rather widely, but over 50% differ by less than the sum of the standard deviations, and the resonance values and GEM10B agree particularly well, apart from the first coefficient  $(\overline{C}_{27}^{0,2})$ . The values from Rapp 1981 and GRIM3-L1 are very similar to each other (probably due to using similar terrestrial gravity data in the solution), and in general do not agree well with the resonance values, except for  $S_{27}^{0,2}$ , though all agree to within about twice the sum of the standard deviations. Thus it can be said that the values from 1973-107B are broadly consistent with the models, but are not accurate enough to provide any significant improvement on the models as a whole.

### 6.2 Geoid height accuracy

The error in geoid height implied by the standard deviations  $\sigma$  of the lumped harmonics may be roughly estimated as  $\text{Ro}/\overline{Q}$ , where R is the Earth's radius and  $\overline{Q} = \{\sum_{k} (Q_{k}^{q,k} \ k_{0}^{2}/k^{2})^{2}\}^{\frac{1}{2}}$ , the summation running from  $\ell_{0}$  up to the maximum  $\ell_{0}$  considered (44 or 45). For  $\overline{C}_{27}^{0,2}$  and  $\overline{S}_{27}^{0,2}$  the value of  $\overline{Q}$  is 1.09 and, with  $\sigma = 4.3 \times 10^{-9}$  as the average, the error in geoid height is about 2.5 cm. For  $\overline{C}_{27}^{1,1}$  and  $\overline{S}_{27}^{1,1}$  the value of  $\overline{Q}$  is 1.75 and, with  $\sigma = 7.1 \times 10^{-9}$  as the average, the error in geoid height is about 2.6 cm. For  $\overline{C}_{27}^{-1,3}$  and  $\overline{S}_{27}^{-1,3}$  the value of  $\overline{Q}$  is 1.26 and, with  $\sigma = 5.0 \times 10^{-9}$  as the average, the error in geoid height is about 2.5 cm.

### 6.3 General discussion

This analysis of 1973-107B is the first known attempt at determining lumped harmonics of order 27 from an orbit passing through 27:2 resonance. However the satellite was not ideal for the purpose, because perigee height was below 400 km and hence drag effects were strong enough to carry the orbit through resonance rather rapidly - about 8 times faster than in Walker's recent analysis of 1968-40B at 29:2 resonance<sup>7</sup>. The accuracy achieved here was therefore expected to be considerably poorer than in Walker's analysis, especially as the effects of the resonance on an orbit are smaller when the satellite's altitude is greater. This expectation is confirmed by the results: in Walker's analysis the best geoid height accuracy was 0.5 cm (though the errors in some harmonics were much larger); here the values are all near 2.5 cm.

The high eccentricity of the orbit also causes problems, and it is possible that the  $q = \pm 2$  terms in equations (4) and (7) may be significant.

The results therefore show that analysis of 27:2 resonance is feasible, but that a less eccentric orbit of considerably lower drag is needed to obtain values of the lumped harmonics that are much better than those available from the comprehensive models of the gravity field.

### 7 CONCLUSIONS

The orbit of 1973-107B has been analysed at 90 epochs from nearly 7400 observations, as it passed through 27:2 resonance between September 1983 and December 1984. The orbital accuracy was good, corresponding to positional accuracies of 130 m cross-track and 80 m in perigee distance.

The variations of inclination and eccentricity have been analysed to determine three pairs of lumped harmonics of order 27, with accuracies equivalent to approximately 2.5 cm in geoid height. These accuracies are of the same order as those of values obtainable from comprehensive gravity field models: to improve on the latter values calls for an orbit of considerably lower drag than 1973-107B, ie having a perigee height well above 400 km.

#### Acknowledgments

I thank Desmond King-Hele for his help with the detailed analysis, Martin Suttie for his work on the early orbit determinations and Bob Gooding for providing values of  $G_{\text{Qpg}}$ .

### 17. Abstract

Aureole 2 rocket (1973-107B) was launched on 26 December 1973 into an orbit of inclination 74° and eccentricity 0.1 and has an estimated lifetime of 30 years. The orbit has been determined from observations for 90 epochs between September 1983 and December 1984, during which time the orbit was expected to be influenced significantly by the effects of 27:2 resonance with the Earth's gravitational field: exact resonance occurred on 28 April 1984. The observations numbered nearly 7400, of which 344 were from the Hewitt cameras of the University of Aston which are sited at Herstmonceux in England, and Siding Spring in Australia. The orbital inclination and eccentricity of the orbits derived had standard deviations corresponding on average to positional accuracies of 130 m cross-track and 80 m in perigee distance.

The variations in inclination and eccentricity have been analysed individually to determine values of two pairs of lumped harmonics of order 27 from each parameter; when these parameters were fitted simultaneously they gave three pairs of harmonics with standard deviations corresponding to accuracies of approximately
